the goal of the asilomar workshop on fault tolerant distributed computing held march 17 19 1986 was to facilitate interaction between theoreticians and practitioners by inviting speakers and choosing topics so as to present a broad overview of the field this volume contains 22 papers stemming from the workshop most of them revised and rewritten presenting research results in distributed systems and fault tolerant architectures and systems the volume should be of use to students researchers and developers

this book presents the most important fault tolerant distributed programming abstractions and their associated distributed algorithms in particular in terms of reliable communication and agreement which lie at the heart of nearly all distributed applications these programming abstractions distributed objects or services allow software designers and programmers to cope with asynchrony and the most important types of failures such as process crashes message losses and malicious behaviors of computing entities widely known under the term byzantine fault tolerance the author introduces these notions in an incremental manner starting from a clear specification followed by algorithms which are first described intuitively and then proved correct the book also presents impossibility results in classic distributed computing models along with strategies mainly failure detectors and randomization that allow us to enrich these models in this sense the

book constitutes an introduction to the science of distributed computing with applications in all domains of distributed systems such as cloud computing and blockchains each chapter comes with exercises and bibliographic notes to help the reader approach understand and master the fascinating field of fault tolerant distributed computing

timo warns has developed tractable fault models that while being non probabilistic are accurate for dependent and propagating faults using seminal problems such as consensus and constructing coteries he demonstrates how the new models can be used to design and evaluate effective and efficient means of fault tolerance

a fundamental question in distributed computing is to determine whether a given set of base shared object types can be used to implement a new type in this thesis we study this problem in a fault tolerant setting where implementations must work even if some of the processes that share the objects may crash an implementation is t resilient if it tolerates the crash of t processes it is wait free if it is n 1 resilient where n is the number of processes this thesis makes two contributions the first concerns the classification of shared object types according to their ability to support wait free implementations a wait free hierarchy assigns object types to levels in 1 2 such that using only objects of any type assigned to level n in conjunction with registers we can implement an object of any type in a wait free manner in a system of n processes such a hierarchy is robust if in a system of n processes it is not possible to implement objects of types at level n in a wait free manner using any number and combination of objects of types that are below level n we show that if nondeterministic types are allowed then the only robust wait free hierarchy is the trivial one which lumps all types into level one one important and useful object type is consensus because consensus objects and registers alone can be used to implement objects of any type the second contribution of the thesis concerns the ability of object types to support one resilient implementations of the type consensus specifically we study the relationship between the one resilient implementability of consensus objects for n processes and that for n 1 processes for every n ge 3 on the one hand the following is shown for n 3 there exists a deterministic type that can be used to implement a one resilient consensus object for three but not two processes on the other hand for every n ge 4 we show that given any set cal b of object types there is a one resilient implementation of a consensus object for n processes using cal b if and only if there is a one resilient implementation of a consensus object for n 1 processes using cal b

understanding distributed computing is not an easy task this is due to the many facets of uncertainty one has to cope with and master in order to produce correct distributed software considering the uncertainty created by asynchrony and process crash failures in the context of message passing systems the book focuses on the main abstractions that one has to understand and master in order to be able to produce software with guaranteed properties these fundamental abstractions are communication abstractions that allow the processes to communicate consistently namely the register abstraction and the reliable broadcast abstraction and the consensus agreement abstractions that allows them to cooperate despite failures as they give a precise meaning to the words communicate and agree despite asynchrony and failures these abstractions allow distributed programs to be designed with properties that can be stated and proved impossibility results are associated with these abstractions hence in order to circumvent these impossibilities the book relies on the failure detector approach and consequently that approach to fault tolerance is central to the book table of contents list of figures the atomic register abstraction implementing an atomic register in a crash prone asynchronous system the uniform reliable broadcast abstraction uniform reliable broadcast abstraction despite unreliable channels the consensus abstraction consensus algorithms for asynchronous systems enriched with various failure detectors constructing failure detectors
