utility based learning from data provides a pedagogical self contained discussion of probability estimation methods via a coherent approach from the viewpoint of a decision maker who acts in an uncertain environment this approach is motivated by the idea that probabilistic models are usually not learned for their own sake rather they are used t

while large data sets have enabled machine learning algorithms to act intelligently in complex domains standard machine learning algorithms perform poorly in situations in which little data exists for the desired target task transfer learning attempts to extract trends from the data of similar source tasks to enhance learning in the target task we apply transfer learning to probabilistic rule learning to learn the dynamics of a target world we utilize a hierarchical bayesian framework and specify a generative model which dictates the probabilities of task data task rulesets and a common global ruleset through a greedy coordinated ascent algorithm the source tasks contribute towards building the global ruleset which can then be used as a prior to supplement the data from the target ruleset simulated experimental results in a variety of blocks world domains suggest that employing transfer learning can provide significant accuracy gains over traditional single task rule learning algorithms

the management of uncertainty in the semantic is of foremost importance given the nature and origin of the available data this book presents a probabilistic semantics for knowledge bases dispointe which is inspired by the distribution semantics of probabilistic logic programming the book also describes approaches for inference and learning in particular it discusses 3 reasoners and 2 learning algorithms bundle and trill are able

to find explanations for queries and compute their probability with regard to disjunctive kbs while trillp compactly represents explanations using a boolean formula and computes the probability of queries the system edge learns the parameters of axioms of disjunctive kbs to reduce the computational cost edgemr performs distributed parameter learning leap learns both the structure and parameters of kbs with leapmr using edgemr for reducing the computational cost the algorithms provide effective techniques for dealing with uncertain kbs and have been widely tested on various datasets and compared with state of the art systems

volume i of the series introduces the general focus of the workshops volume ii looks at specific areas of interaction between theory and experiment volumes iii and iv focus on key areas of learning systems that have developed recently volume iii looks at the problem of selecting good models the present volume volume iv looks at ways of making learning systems practical the editors divide the twenty one contributions into four sections the first three cover critical problem areas 1 scaling up from small problems to realistic ones with large input dimensions 2 increasing efficiency and robustness of learning methods and 3 developing strategies to obtain good generalization from limited or small data samples the fourth section discusses examples of real world learning systems

this book proposes probabilistic machine learning models that represent the hardware properties of the device hosting them these models can be used to evaluate the impact that a specific device configuration may have on resource consumption and performance of the machine learning task with the overarching goal of balancing the two optimally the book first motivates extreme edge computing in the context of the internet of things iot paradigm then it briefly reviews the steps involved in the execution of a machine learning task and identifies the implications associated with implementing this type of workload in resource constrained devices the core of this book focuses on augmenting and exploiting the properties of bayesian networks and probabilistic circuits in order to endow them with hardware awareness the proposed models can encode the properties of various device sub systems that are typically not considered by other resource aware strategies bringing about resource saving opportunities that traditional approaches fail to uncover the performance of the proposed models and strategies is empirically evaluated for several use cases all of the considered examples show the potential of attaining significant resource saving opportunities with minimal accuracy losses at application time overall this book constitutes a novel approach to hardware algorithm co optimization that further bridges the fields of machine learning and electrical engineering

probabilistic graph based models such as bayesian and markov networks are used to represent and reason about uncertainty in many real world domains since most inference or reasoning tasks over them are np hard in general the following two strategies are used in practice to combat the intractability of exact inference first a potentially intractable model is learned from data and then polynomial time approximate inference algorithms e g belief propagation gibbs sampling etc are used at inference time to trade accuracy with computational complexity second strong constraints are imposed on the models e g tree structure at learning time such that exact inference is tractable and then exact algorithms are used

at inference time inspired by the work in the tractable probabilistic models community who use the latter approach in this dissertation we propose algorithms that learn models on which exact or approximate inference or both are computationally efficient as well as accurate we call such algorithms inference guided learning igl algorithms to date we have developed four novel igl algorithms investigated their theoretical properties and empirically evaluated their practical performance our first algorithm induces a cutset network a probabilistic model that admits linear time full maximum a posteriori map inference in addition to linear time posterior marginal mar inference this algorithm alleviates the following shortcoming in existing work on tractable probabilistic models the learned models are such that exact mar inference is tractable but full map inference is not and as a result they exhibit poor performance for the latter query type our second algorithm learns more accurate discriminative or conditional cutset networks ccns from data these networks yield more accurate answers to full map and mar queries under the assumption that a fixed subset of variables in the application domain is always observed our third algorithm induces probabilistic models on which rao blackwellised importance sampling a popular simulation based inference scheme is likely to perform well finally our fourth algorithm focuses on using local information to improve the quality of tractable models unlike global information local information is available in plenty but is susceptible to noise and therefore our proposed method filters noise in a principled manner

machine learning approaches have traditionally made strong simplifying assumptions that a benevolent teacher is available to present and classify instances of a single concept to be learned that no noise or uncertainty is present in the environment that a complete and correct domain theory is available or that a useful language is provided by the designer additional much existing machine learning research has been done in a piecemeal fashion addressing subproblems without a uniform conceptual approach to designing intelligent systems the resulting learning techniques often are only useful for narrowly defined problems and are so dependent on the underlying assumptions that they do not generalize well or at all to complex domains pagoda probabilistic autonomous goal directed agent the intelligent agent design presented in this thesis avoids making any of the above assumptions it incorporates solutions to the problems of deciding what to learn selecting a learning bias and inductive
