linear algebra and matrix theory are fundamental tools in mathematical and physical science as well as fertile fields for research this second edition of this acclaimed text presents results of both classic and recent matrix analysis using canonical forms as a unifying theme and demonstrates their importance in a variety of applications this thoroughly revised and updated second edition is a text for a second course on linear algebra and has more than 1 100 problems and exercises new sections on the singular value and cs decompositions and the weyr canonical form expanded treatments of inverse problems and of block matrices and much more

in this book the authors present classical and recent results for matrix analysis that have proved to be important to applied mathematics facts about matrices beyond those found in an elementary linear algebra course are needed to understand virtually any area of mathematics and the necessary material has only occurred sporadically in the literature and university curricula as the interest in applied mathematics has grown the need for a text and a reference work offering a broad selection of topics has become apparent and this book aims to meet that need this book will be welcomed as an undergraduate or graduate textbook for students studying matrix analysis the authors assume a background in elementary linear algebra and knowledge of rudimentary analytical concepts they begin with a review and discussion of eigenvalues and eigenvectors the following chapters each treat a major topic in depth this volume should be useful not only as a text but also as a self contained reference work to a variety of audiences in other scientific fields

building on the foundations of its predecessor volume matrix analysis this book treats in detail several topics in matrix theory not included in the previous volume but with important applications and of special mathematical interest as with the previous volume

the authors assume a background knowledge of elementary linear algebra and rudimentary analytical concepts many examples and exercises of varying difficulty are included

the thoroughly revised and updated second edition of this acclaimed text has several new and expanded sections and more than 1 100 exercises

linear algebra and matrix theory are fundamental tools in mathematical and physical science as well as fertile fields for research this new edition of the acclaimed text presents results of both classic and recent matrix analysis using canonical forms as a unifying theme and demonstrates their importance in a variety of applications the authors have thoroughly revised updated and expanded on the first edition the book opens with an extended summary of useful concepts and facts and includes numerous new topics and features such as new sections on the singular value and cs decompositions new applications of the jordan canonical form a new section on the weyr canonical form expanded treatments of inverse problems and of block matrices a central role for the von neumann trace theorem a new appendix with a modern list of canonical forms for a pair of hermitian matrices and for a symmetric skew symmetric pair expanded index with more than 3 500 entries for easy reference more than 1 100 problems and exercises many with hints to reinforce understanding and develop auxiliary themes such as finite dimensional quantum systems the compound and adjugate matrices and the loewner ellipsoid a new appendix provides a collection of problem solving hints

using a modern matrix based approach this rigorous second course in linear algebra helps upper level undergraduates in mathematics data science and the physical sciences transition from basic theory to advanced topics and applications its clarity of exposition together with many illustrations 900 exercises and 350 conceptual and numerical examples aid the student s understanding concise chapters promote a focused progression through essential ideas topics are derived and discussed in detail including

the singular value decomposition jordan canonical form spectral theorem qr factorization normal matrices hermitian matrices and positive definite matrices each chapter ends with a bullet list summarizing important concepts new to this edition are chapters on matrix norms and positive matrices many new sections on topics including interpolation and lu factorization 300 more problems many new examples and color enhanced figures prerequisites include a first course in linear algebra and basic calculus sequence instructor s resources are available

what s in a name to paraphrase shakespeare s juliet that which ilie haynsworth called the schur complement by any other name would be just as beautiful nevertheless her 1968 naming decision in honor of issai schur 1875 1941 has gained lasting acceptance by the mathematical community the schur complement plays an important role in matrix analysis statistics numerical analysis and many other areas of mathematics and its applications our goal is to expose the schur complement as a rich and basic tool in mathematical research and applications and to discuss many significant results that illustrate its power and fertility although our book was originally conceived as a research reference it will also be useful for graduate and upper division undergraduate courses in mathematics applied mathematics and statistics the contributing authors have developed an exposition that makes the material accessible to readers with a sound foundation in linear algebra the eight chapters of the book chapters 0 7 cover themes and variations on the schur complement including its historical development basic properties eigenvalue and singular value inequalities matrix inequalities in both finite and infinite dimensional settings closure properties and applications in statistics probability and numerical analysis the chapters need not be read in the order presented and the reader should feel at leisure to browse freely through topics of interest

the study of euclidean distance matrices edms fundamentally asks what can be known geometrically given only distance information between points in euclidean space each point may represent simply location or abstractly any entity expressible as a vector in finite

dimensional euclidean space the answer to the question posed is that very much can be known about the points the mathematics of this combined study of geometry and optimization is rich and deep throughout we cite beacons of historical accomplishment the application of edms has already proven invaluable in discerning biological molecular conformation the emerging practice of localization in wireless sensor networks the global positioning system gps and distance based pattern recognition will certainly simplify and benefit from this theory we study the pervasive convex euclidean bodies and their various representations in particular we make convex polyhedra cones and dual cones more visceral through illustration and we study the geometric relation of polyhedral cones to nonorthogonal bases biorthogonal expansion we explain conversion between halfspace and vertex descriptions of convex cones we provide formulae for determining dual cones and we show how classic alternative systems of linear inequalities or linear matrix inequalities and optimality conditions can be explained by generalized inequalities in terms of convex cones and their duals the conic analogue to linear independence called conic independence is introduced as a new tool in the study of classical cone theory the logical next step in the progression linear affine conic any convex optimization problem has geometric interpretation this is a powerful attraction the ability to visualize geometry of an optimization problem we provide tools to make visualization easier the concept of faces extreme points and extreme directions of convex euclidean bodies is explained here crucial to understanding convex optimization the convex cone of positive semidefinite matrices in particular is studied in depth we mathematically interpret for example its inverse image under affine transformation and we explain how higher rank subsets of its boundary united with its interior are convex the chapter on geometry of convex functions observes analogies between convex sets and functions the set of all vector valued convex functions is a closed convex cone included among the examples in this chapter we show how the real affine function relates to convex functions as the hyperplane relates to convex sets here also pertinent results for multidimensional convex functions are presented that are largely ignored in the literature tricks and tips for determining their convexity and

discerning their geometry particularly with regard to matrix calculus which remains largely unsystematized when compared with the traditional practice of ordinary calculus consequently we collect some results of matrix differentiation in the appendices the euclidean distance matrix edm is studied its properties and relationship to both positive semidefinite and gram matrices we relate the edm to the four classical axioms of the euclidean metric thereby observing the existence of an infinity of axioms of the euclidean metric beyond the triangle inequality we proceed by deriving the fifth euclidean axiom and then explain why furthering this endeavor is inefficient because the ensuing criteria while describing polyhedra grow linearly in complexity and number some geometrical problems solvable via edms edm problems posed as convex optimization and methods of solution are presented eg we generate a recognizable isotonic map of the united states using only comparative distance information no distance information only distance inequalities we offer a new proof of the classic schoenberg criterion that determines whether a candidate matrix is an edm our proof relies on fundamental geometry assuming any edm must correspond to a list of points contained in some polyhedron possibly at its vertices and vice versa it is not widely known that the schoenberg criterion implies nonnegativity of the edm entries proved here we characterize the eigenvalues of an edm matrix and then devise a polyhedral cone required for determining membership of a candidate matrix in cayley menger form to the convex cone of euclidean distance matrices edm cone ie a candidate is an edm if and only if its eigenspectrum belongs to a spectral cone for edm n we will see spectral cones are not unique in the chapter edm cone we explain the geometric relationship between the edm cone two positive semidefinite cones and the elliptope we illustrate geometric requirements in particular for projection of a candidate matrix on a positive semidefinite cone that establish its membership to the edm cone the faces of the edm cone are described but still open is the question whether all its faces are exposed as they are for the positive semidefinite cone the classic schoenberg criterion relating edm and positive semidefinite cones is revealed to be a discretized membership relation a generalized inequality a new farkas like lemma between the edm cone and its

ordinary dual a matrix criterion for membership to the dual edm cone is derived that is simpler than the schoenberg criterion we derive a new concise expression for the edm cone and its dual involving two subspaces and a positive semidefinite cone semidefinite programming is reviewed with particular attention to optimality conditions of prototypical primal and dual conic programs their interplay and the perturbation method of rank reduction of optimal solutions extant but not well known we show how to solve a ubiquitous platonic combinatorial optimization problem from linear algebra the optimal boolean solution x to $ax \leq b$ via semidefinite program relaxation a three dimensional polyhedral analogue for the positive semidefinite cone of 3×3 symmetric matrices is introduced a tool for visualizing in 6 dimensions in edm proximity we explore methods of solution to a few fundamental and prevalent euclidean distance matrix proximity problems the problem of finding that euclidean distance matrix closest to a given matrix in the euclidean sense we pay particular attention to the problem when compounded with rank minimization we offer a new geometrical proof of a famous result discovered by eckart young in 1936 regarding euclidean projection of a point on a subset of the positive semidefinite cone comprising all positive semidefinite matrices having rank not exceeding a prescribed limit ρ we explain how this problem is transformed to a convex optimization for any rank ρ
