the existence and crucial role played by large scale organized motions in turbulent flows are now recognized by industrial applied and fundamental researchers alike it has become increasingly evident that coherent structures

influence mixing noise vibration heat transfer drag etc the acceleration of the development of both experimental and computational programs devoted to this topic has been evident at several recent international meetings one of the first questions which experimentalists or numerical analysts are faced with is how can these structures be separated from the background turbulence this is a nontrivial task because the coherent structures are generally embedded in a random field and the technique used to determine when and where certain structures are passing or their averaged characteristics in the more probable or dominant role sense is directly related to the definition of the coherent structure several methods or approaches are available and the choice of a particular one is generally dependent on the desired information this choice depends not only on the definition of the structure but also on the experimental and numerical capabilities available to the researcher
